pb2: bring search algorithm onlys search at one Side of the list element is compared with the middle element if large search night if smaller rearch left if equal tormid element return true and if not he tem fastre. mote: work above at each step i is I which is comparing
the mid element with the given number to be searched the wast case in this algorithm is if we are looking for element that demot exist on the tree 1 at each level one there is O(4) work done and hight afthe tree is (dogn) T(n) = 0(1 x lgn) =0 (l-gm).

Problem 3: necurive algorith to reverse order Algorithm nevere order Imput any of melements output: anay of relevants in revesed order of start > end then return to Hotenp = A [stant) A [start ] = A [end] A [end] eten? never & Order (A, start + 1, end - 4) T(n-c) compute the & rusming time worky count self calls in the given algorithm we can observe that the mext method recursive call is smaller by e, then the first one because start+1 and end-1 T(n) Se n= because we do It have formula to resolve this we will use the free method
